Numerical Solution of Maxwell's Equations  
Two Time-Level Difference Scheme TTLD  
F. Hassan

Abstract:

This paper deals with numerical approximations of electromagnetic phenomena, which described by Maxwell's equations. A two time-level difference scheme (TTLD) is introduced for solving Maxwell’s equation as wave equation; this is to reduce the large computational and storage costs of Yee scheme. Convergence and stability conditions have been studied. The comparison with Yee scheme is presented.

1- Introduction

Maxwell's equations have many important implications in the life of a modern person. The principles of electromagnetism have been deduced from experimental observations. These principles are Faraday's law, Ampere's law and Gauss's laws for electric and magnetic fields. These equations had appeared throughout James Clerk Maxwell's 1861. Those equations describe the interrelationship between electric field, magnetic field, electric charge, and electric current, [5] and [13]. This alteration in Ampere's law provides that a changing electric flux produces a magnetic field, just as Faraday's law provides that a changing magnetic field produces an electric field. The relationships of electricity and magnetism are called Maxwell's equations, [10]. The exact solution of Maxwell's system is very complicated or even impossible; this is why numerical methods are generally applied. The first and still applied method is the Finite Difference Time Domain (FDTD) constructed by K. Yee in 1966. Despite the simplicity of the scheme, it requires large computational and storage costs, [1] and [3].

2- Maxwell's Equations

Let $\Omega \times T$ be the Cartesian product of a bound simply-connected domain $\Omega$ and a non-negative time interval $T$. Let $\Omega$, have a smooth or a polygonal boundary $\Gamma$. Electromagnetic phenomenon in $\Omega \times T$ can be described by the differential equations

$$\nabla \times E = -\frac{\partial B}{\partial t} \quad \text{In} \quad \Omega \times T \quad (1)$$

$$\nabla \times H = \frac{\partial D}{\partial t} + j \quad \text{In} \quad \Omega \times T \quad (2)$$

With the linear material; constitutive relations

$$\begin{cases}
D = \varepsilon E \\
B = \mu H \\
j = \sigma E
\end{cases} \quad \text{In} \quad \Omega \times T$$

Coupled with Gauss's law

$$\nabla \cdot B = 0 \quad \text{(3)}$$

$$\nabla \cdot D = \rho \quad \text{(4)}$$

Equation (1) and equation (2) are Faraday and Amper's laws of Maxwell's equations. E is the electric field, H is the magnetic field, J is the total electric current density, $\mu$ is the magnetic permeability, we assume that...
the magnetic permeability does not depend on time and \( \varepsilon \) is the electric permittivity, in vacuum we have \( c = 1 / \sqrt{\mu_0 \varepsilon_0} \). The electric permittivity is also assumed not depend on time, \( \sigma \) is the electric conductivity, its value is non-negative for dissipative structures [1], [3], [10], [11], [12] and [13]. Both \( E \) and \( H \) are vectors in three dimensions, and then equation (1) and equation (2) can be written as

\[
\begin{pmatrix}
\frac{\partial E_x}{\partial t} \\
\frac{\partial E_y}{\partial t} \\
\frac{\partial E_z}{\partial t}
\end{pmatrix}
= \frac{1}{\varepsilon} \begin{pmatrix}
\frac{\partial H_z}{\partial y} - \frac{\partial H_y}{\partial z} \\
\frac{\partial H_x}{\partial z} - \frac{\partial H_z}{\partial x} \\
\frac{\partial H_y}{\partial x} - \frac{\partial H_x}{\partial y}
\end{pmatrix} - \sigma \begin{pmatrix}
E_x \\
E_y \\
E_z
\end{pmatrix}
\]  

(5)

\[
\begin{pmatrix}
\frac{\partial H_x}{\partial t} \\
\frac{\partial H_y}{\partial t} \\
\frac{\partial H_z}{\partial t}
\end{pmatrix}
= -\frac{1}{\mu} \begin{pmatrix}
\frac{\partial E_z}{\partial y} - \frac{\partial E_y}{\partial z} \\
\frac{\partial E_x}{\partial z} - \frac{\partial E_z}{\partial x} \\
\frac{\partial E_y}{\partial x} - \frac{\partial E_x}{\partial y}
\end{pmatrix}
\]  

(6)

Since the electric field and magnetic field travel perpendicular to one another, thus their dot product must be zero. The solution of Maxwell's equations means the computation of the field strengths using the material parameters and some initial and boundary conditions. For simplicity we suppose that there are no conductive currents and free charges in the computational domain, thus we must solve only the system consisting of equation (1) and equation (2) without electric conductive current density, [7]. The magnetic field well be constrained to two dimensional (x-y)-plane. The electric field is then constrained to the z direction. Hence equation (5) and equation (6) become

\[
\varepsilon \frac{\partial E_z}{\partial t} = \frac{\partial H_y}{\partial x} - \frac{\partial H_x}{\partial y}
\]  

(7)

\[
\mu \frac{\partial H_x}{\partial t} = -\frac{\partial E_z}{\partial y}
\]  

(8)

\[
\mu \frac{\partial H_y}{\partial t} = \frac{\partial E_z}{\partial x}
\]  

(9)

The above set of equations usually referred to as the transverse magnetic (TM) mode [10]. Most (FDTD) scheme solves the time-dependent Maxwell equations using algorithms based on Yee scheme. A limitation of Yee scheme techniques is that their stability is conditional, [7].

3-Finite-Difference Time-Domain Method (FDTD)

The time-dependent Maxwell's equations (in partial differential form) are discredited using central-difference approximations to the space and time partial derivatives. The resulting finite-difference equations are solved in a leapfrog manner. The electric field vector components in a volume of space are solved at a given instant in time, then the magnetic field vector components in the same spatial volume are solved at the next instant in time; and the process is repeated over and over again until stop. [1], [3], [9], [10], [13], and [14].
Two Time-Level Finite Difference Scheme (TTLD)

In this paper, Maxwell's equations are solved using a simple finite difference scheme without using leapfrog manner. The solution is computed as follows.

1. Elimination of H (or E) in equation (1) and equation (2) to obtain the wave equation (This is to reduce the large computational and storage costs of Yee scheme).
2. Determine a finite difference scheme which will be used to solve the reduced set of equations.
3. Studying convergence, consistency and stability for the proposed scheme.

4.1 The Wave Equation

4. If we take the time derivative of Faraday and Ampere's in Maxwell's equation and assume that the material properties are time independent, we obtain

\[ \varepsilon \frac{\partial^2 E_z}{\partial t^2} = \frac{\partial}{\partial x} \left( \frac{\partial H_y}{\partial t} - \frac{\partial}{\partial y} \frac{\partial H_x}{\partial t} \right) \]
\[ \varepsilon \frac{\partial^2 E_z}{\partial t^2} = \frac{\partial}{\partial x} \left( \frac{1}{\mu} \frac{\partial E_z}{\partial y} \right) - \frac{\partial}{\partial y} \left( \frac{1}{\mu} \frac{\partial E_z}{\partial x} \right) \]

This reduces to

\[ \frac{\partial^2 E_z}{\partial t^2} = c^2 \left( \frac{\partial^2 E_z}{\partial x^2} + \frac{\partial^2 E_z}{\partial y^2} \right) \]  
\[ (10) \]

Where \( c = 1/\sqrt{\varepsilon \mu} \) is the speed of propagation for the electromagnetic wave. In a similar manner,

\[ \frac{\mu}{c^2} \frac{\partial}{\partial t} \frac{\partial E_z}{\partial y} = \frac{\partial}{\partial x} \left( \frac{\partial H_x}{\partial t} - \frac{\partial H_y}{\partial t} \right) \]
\[ \frac{\partial^2 H_x}{\partial t^2} = c^2 \left( \frac{\partial^2 H_x}{\partial y^2} - \frac{\partial^2 H_y}{\partial y \partial x} \right) \]  
\[ (11) \]

by the same way

\[ \frac{\partial^2 H_y}{\partial t^2} = c^2 \left( \frac{\partial^2 H_y}{\partial x^2} - \frac{\partial^2 H_x}{\partial y \partial x} \right) \]  
\[ (12) \]

Now, equation (10) is used to find approximate solution for electric field in \( z \) direction. Equations (11) and (12) are used together to find an approximate solution of the magnetic field. By using equation (10) we can find approximate solution of \( E_z \) at a new time if we know the values of \( E_z \) at the boundary, and \( E_z \) and \( \frac{\partial E_z}{\partial t} \) at the initial time. By using the central difference approximation in both side of equation (10), we may show that

\[ (E_z)^{k+1}_{i,j} = r[(E_z)^k_{i+1,j} + (E_z)^k_{i-1,j}] + (2 - 4r)(E_z)^k_{i,j} + r[(E_z)^k_{i,j+1} + (E_z)^k_{i,j-1}] - (E_z)^k_{i,j} \]  
\[ (13) \]

Where \( r = \left( \frac{\Delta t c}{\varepsilon} \right)^2 = \frac{\Delta t^2}{h^2 \varepsilon} \). Equation (13) gives a formula for the unknown electric field \( (E_z)^{k+1}_{i,j} \) at \( (i, j, k+1)^{th} \) mesh point in terms of known electric field along the \( k^{th} \) and \( (k-1)^{th} \) time rows.
Analysis study

This section is concerned with the conditions that must be satisfied if the solution of the finite-difference equations is to be reasonably accurate approximation to the solution of the corresponding partial differential equation.

4.2.1 The Stability of TTLD Scheme

The vector solution \( E^{k+1} \) of the finite difference equations at the \((k+1)^{th}\) time-level is related to the vectors solution \( E^k \) and \( E^{k-1} \) at the \(k^{th}\) and \((k-1)^{th}\) time-levels respectively by the following equation.

\[
\begin{pmatrix}
E^{k+1}_{i,1} \\
\vdots \\
E^{k+1}_{i,N-1}
\end{pmatrix} = \begin{pmatrix}
D & R \\
R & D & R \\
\vdots & \ddots & \ddots & \ddots \\
R & D & E^{k}_{i,1} & E^{k}_{i,j} & \ldots & E^{k}_{i,N-1} \\
\vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots \\
R & D & E^{k}_{i,1} & E^{k}_{i,j} & \ldots & E^{k}_{i,N-1} & E^{k-1}_{i,1} & E^{k-1}_{i,j} & \ldots & E^{k-1}_{i,N-1} \\
\vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots \\
R & D & E^{k}_{i,1} & E^{k}_{i,j} & \ldots & E^{k}_{i,N-1} & E^{k-1}_{i,1} & E^{k-1}_{i,j} & \ldots & E^{k-1}_{i,N-1} & C^k_{i,1} & \ldots & C^k_{i,N-1}
\end{pmatrix}
\]

where \( C \) is a vector of known values, \( i=1,\ldots,N-1, j=1,\ldots,N-1 \) and \( k=1,2,\ldots,T \). Equation (14) can be written as

\[
E^{k+1} = AE^k - E^{k-1} + C^k
\]  

(15)

Where \( A \) is \((N-1)^2 \times (N-1)^2\) blocktridiagonal matrix as is displayed. Each \( D \) and \( R \) are \((N-1) \times (N-1)\) matrix have the following form

\[
D = \begin{pmatrix}
(2-4r) & r & \ldots & \ldots \\
\vdots & \ddots & \ddots & \ddots \\
r & (2-4r) & r & \ldots \\
\ldots & \ddots & \ddots & \ddots \\
r & \ldots & r & (2-4r)
\end{pmatrix}
\]

\[
R = r \ I
\]

Equation (13) can be written as

\[
\begin{pmatrix}
E^{k+1} \\
E^k
\end{pmatrix} = \begin{pmatrix}
A & -I \\
I & O
\end{pmatrix} \begin{pmatrix}
E^k \\
E^{k-1}
\end{pmatrix} + \begin{pmatrix}
C^k \\
O
\end{pmatrix}
\]

(16)

where \( I \) is the unit matrix of order \((N-1)^2\). This technique has reduced a three-level difference equation to two-level one, [2] and [4].

\[
P = \begin{pmatrix}
A & -I \\
I & O
\end{pmatrix}
\]

Equation (16) will be stable when each Eigen value of \( P \) has a modules \( \leq 1 \). The matrix \( A \) has \((N-1)^2\) different eigenvalues. Also the matrix \( I \) has \((N-1)^2\) eigenvalues each equal \( I \). Hence the eigenvalues \( \lambda \) of \( P \) are the eigenvalues of the matrix

\[
\begin{pmatrix}
\hat{\lambda}_s & -1 \\
1 & 0
\end{pmatrix}
\]

where \( \hat{\lambda}_s \) is the \( S^{th} \) Eigen value of \( A \). The eigenvalues of \( A \) are given by the eigenvalues of matrices
Where $\lambda_D^{(s)}$ are the $s^{th}$ Eigen value of $D$, and $\lambda_R^{(s)}$ the $s^{th}$ eigenvalue of $R$. Then

$$\lambda_D = (2 - 4r) + 2r \cos \frac{s\pi}{N}, \quad s = 1,2,\ldots,N - 1$$

$$\lambda_R^{(s)} = r$$

$$\lambda_s = (2 - 4r) + 4r \cos \frac{s\pi}{N}$$

For such case we can find $\lambda$ by evaluating

$$\det \begin{bmatrix} \lambda - \lambda_s & -1 \\ 1 & -\lambda \end{bmatrix} = 0$$

i.e.,

$$\lambda = \frac{1}{2}(\lambda_s \pm \sqrt{-4 + \lambda_s^2})$$

We want to see under what condition, $|\lambda_{\pm}| \leq 1$, two possible cases have been considered.

**Case 1:**

If $\lambda_s^2 \leq 4$ then $\lambda$ is complex, then $-1 \leq -r(1 - \cos \frac{s\pi}{N}) \leq 0$

Therefore TTLD scheme is stable for all $0 < r \leq \frac{1}{2}$, then the time increment must satisfy the condition

$$\Delta t \leq \frac{h}{\sqrt{2c}}$$

**Case 2:**

If $\lambda_s^2 \geq 4$ then $\lambda$ is real $|\lambda_{\pm}|^2 > 1$, In this case the scheme is unstable

### 4.2.2 Analytical treatment of consistency

The convergence of the solution of an approximating set of linear difference equations, (13), to the solution of a linear partial differential equation (10), can be investigated directly by deriving a difference equation for the discretization error $e$.

Denote the exact solution of the partial differential equation by $E_{\text{exct}}$ and the exact solution of the finite difference equation by $E_z$. Then $e = E_{\text{exct}} - E_z$, i.e. $(E_z)^{k}_{i,j} = (E_{\text{exct}})^{k}_{i,j} - e^{k}_{i,j}$,

$$(E_z)^{k+1}_{i,j} = (E_{\text{exct}})^{k+1}_{i,j} - e^{k+1}_{i,j} \ldots \ldots \text{etc}$$

Substitution into equation (13), and by Taylor’s expansion, leads to

$$e^{k+1}_{i,j} = r[e^{k+1}_{i+1,j} + e^{k+1}_{i-1,j}] + (2 - 4r)e^{k}_{i,j} + r[e^{k+1}_{i+1,j} + e^{k+1}_{i-1,j}] - e^{k-1}_{i,j}$$

$$+ \frac{\Delta t^2}{12} \left( \frac{\partial^4 E_{\text{exct}}}{\partial t^4} - \frac{h^2}{\mu} \left( \frac{\partial^4 E_{\text{exct}}}{\partial x^4} + \frac{\partial^4 E_{\text{exct}}}{\partial y^4} \right) \right) + \ldots$$
\begin{equation}
\left| e_{i,j}^{k+1} \right| \leq r \left[ e_{i+1,j}^{k} + e_{i-1,j}^{k} \right] + (2 - 4r) e_{i,j}^{k} + r \left[ e_{i,j+1}^{k} + e_{i,j-1}^{k} \right] - e_{i,j}^{k-1} \\
+ \frac{\Delta t^2}{12} M \left( \Delta t^2 - \frac{h^2}{\mu} \right) \\
\left| e^{k+1} \right| \leq 2 \left| e^{k} \right| - \left| e^{k-1} \right| + \frac{\Delta t^2}{12} M \left( \Delta t^2 - \frac{h^2}{\mu} \right)
\end{equation}

Where \( M \) is the modules of the largest of \( \frac{\partial^4 E_{\text{exact}}}{\partial x^4} \), \( \frac{\partial^4 E_{\text{exact}}}{\partial y^4} \) and \( \frac{\partial^4 E_{\text{exact}}}{\partial t^4} \) and \( e^{k} \) and \( e^{k-1} \) are the maximum error at \( k^{th} \) and \( (k-1)^{th} \) time-level, respectively. Then we can prove that

\begin{equation}
\left| e^{k+1} \right| \leq \frac{1}{2} (k + 1) \left( 2 \left| e^{1} \right| + \frac{k \Delta t^2}{12} M \left( \Delta t^2 - \frac{h^2}{\mu} \right) \right) - k \left| e^{0} \right|
\end{equation}

If the values of \( \left( E_{\text{z}} \right)^0_{i,j} \) and \( \left( \frac{\partial E_{\text{z}}}{\partial t} \right)^0_{i,j} \) are known at initial time, then

\begin{align*}
\left( E_{\text{z}} \right)^1_{i,j} &= \left( E_{\text{z}} \right)^0_{i,j} + \Delta t g_{i,j}, \text{where} \left( \frac{\partial E_{\text{z}}}{\partial t} \right)^0_{i,j} = g_{i,j} \\
\left( E_{\text{exact}} \right)^1_{i,j} &= \left( E_{\text{exact}} \right)^0_{i,j} + \Delta t \left( \frac{\partial E_{\text{exact}}}{\partial t} \right)^0_{i,j} + \frac{\Delta t^2}{2!} \left( \frac{\partial^2 E_{\text{exact}}}{\partial t^2} \right)^0_{i,j} + O(\Delta t^4)
\end{align*}

\begin{equation}
\left| e^{1} \right| = \left| E_{\text{exact}} - E_{\text{z}} \right| \leq \frac{\Delta t^2}{2} M_i + \left| e^{0} \right|
\end{equation}

where

\begin{equation}
M_i = \text{Max} \left[ \frac{\partial^2 E_{\text{exact}}}{\partial t^2} + O(\Delta t^2) \right]
\end{equation}

then

\begin{equation}
\left| e^{k+1} \right| \leq \frac{1}{2} (k + 1) \Delta t^2 \left( M_i + \frac{k}{12} M \left( \Delta t^2 - \frac{h^2}{\mu} \right) \right) \left| e^{0} \right|
\end{equation}

i.e., \( E_{\text{z}} \) converges to the exact solution as \( \Delta t \) and \( h \) tends to zero.

### 4 Computational Cost Comparisons

We consider a test case with the following boundary and initial conditions:

\( E_{\text{z}}(x, y, 0) = \sin(3\pi x) \sin(4\pi y) \)
\( \frac{\partial}{\partial t} E_{\text{z}}(x, y, 0) = 0 \)
\( E_{\text{z}}(0, y, t) = 0 \)
\( E_{\text{z}}(1, y, t) = \sin(3\pi) \sin(4\pi y) \cos(5\pi t) \)
\( E_{\text{z}}(x, 0, t) = 0 \)
The exact solution in this case is:

\[ E_z(x, y, t) = \sin(3\pi x) \sin(4\pi y) \cos(5\pi t) \]

For the two schemes we choose uniform grid spacing with \( \Delta x = \Delta y = h, \quad \Delta t = h^2 \). The error in \( L_2 \) norm for the two schemes is measured at the same time. The comparison is shown in tables (1:4). The programs were written in MATHEMATICA 5.2 and run on IBM PC (160 MHZ).

6 Conclusion

The present study shows that the CPU time needed to achieve the same accuracy in Yee scheme is more than two times larger than required for TTLD scheme, this is due to the large computational and storage costs of Yee scheme.
